

CIRS ICY Satellite  
Target NOTEBOOK

## Foreword

The purpose of the target notebook is to provide the end user with a “one stop shop” for information about the target from a CIRS perspective – from the planning of each observation and its science intent to collection of the data and its quality. The goal of this effort is to enable better use of the CIRS dataset archived at the Planetary Data System.

The notebook contains the following sections: Introduction, Planning, Data Collection, Database Contents, and Publications/Science Research generated by the dataset. The Introduction section discusses the science objectives, descriptions of the observation types and their intent. The Planning section contains a time ordered listing of all the observations planned with a suite of supporting files that provide plots, pointing, and instrument commanding for each observation. The Data Collection section provides the user with information about the data that was collected with a comparison to what was planned and a commentary on any lost data. The Database contents section provides a discussion of the data in the database at PDS at a high level – what was calibrated, what was not, and why as well as a brief commentary the challenges in calibrating the data. The final section – Publications/Science Research provides the user with a list of publications for the target, a high level description of the science analysis undertaken with contact information for those CIRS team members involved.

## Introduction

Due to the nature of icy satellite science most of the observations are unique, depending on geometry of the flyby and the time allocated to each remote sensing instrument. This means there isn't templates for icy satellite encounter observations made by CIRS.

The observation sequence of each icy satellite encounter was negotiated through the Cassini Satellite Orbiter Science Team (SOST), which had monthly telecons. The SOST negotiations were pretty civilized, largely because most remote sensing instruments could design observations that allowed other instruments to ride along with them. Furthermore, not all time slots were useful to all instruments (e.g. nighttime observations weren't useful to VIMS).

*[Do you need info on what FP1/3/4 are? I figured that would be covered elsewhere, but see Conor included it.]*

Despite the lack of templates CIRS did adopt some typical observing principles. The most important one was that typically CIRS used focal plane 1 (FP1) for nighttime observations, and focal planes 3 and 4 (FP3 and FP4) for daytime observations. This is because only FP1 is sensitive to the cold icy satellite nighttime surface temperatures (typically <60 K). FP3 has almost twice the spatial resolution of FP1, however it was only sensitive to temperatures >60 K meaning it could only be used for daytime observations (and observations of Enceladus' active regions and the dark regions of Iapetus). FP4 is only sensitive to even warmer temperatures (greater than ~110 K), which makes it only useful for the warmest scenes (for icy satellite science this in practice meant Enceladus' active regions, but it was used for daytime observations of icy surfaces too but considered redundant over FP3).

Enceladus' active region was observed differently. The high-surface temperatures meant this region was observable by all three focal planes, and often FP3 and FP4 were prioritized since they provide higher spatial resolution than FP1. Again the exact nature of these observations depended upon the geometry of the encounter and the science that was trying to be achieved. Sometimes the detectors were dragged along a single fracture, while other times they were swept across all of them.

The emission from the icy satellites is largely just its blackbody emission. This meant that mostly CIRS observed at low spectral resolutions, so that it could scan faster (the higher the spectral resolution the

longer a single scan took). Most observations were made at  $15\text{ cm}^{-1}$  wavenumber resolution, however some were made at  $3\text{ cm}^{-1}$  to look for emissivity variations

### FP1 observing strategies.

#### *Raster Scans*

Since FP1 mainly took nighttime observations (which are of little/no use to rider instrument such as VIMS) we could use a fast scan rate, typically  $40\text{ }\mu\text{rad/s}$ , FP1 is a single detector (unlike FP3 and FP4) so a picture of the target had to be build up using raster scanning. Typically this was set to allow Nyquist sampling. A typical scan is given in Figure 1.

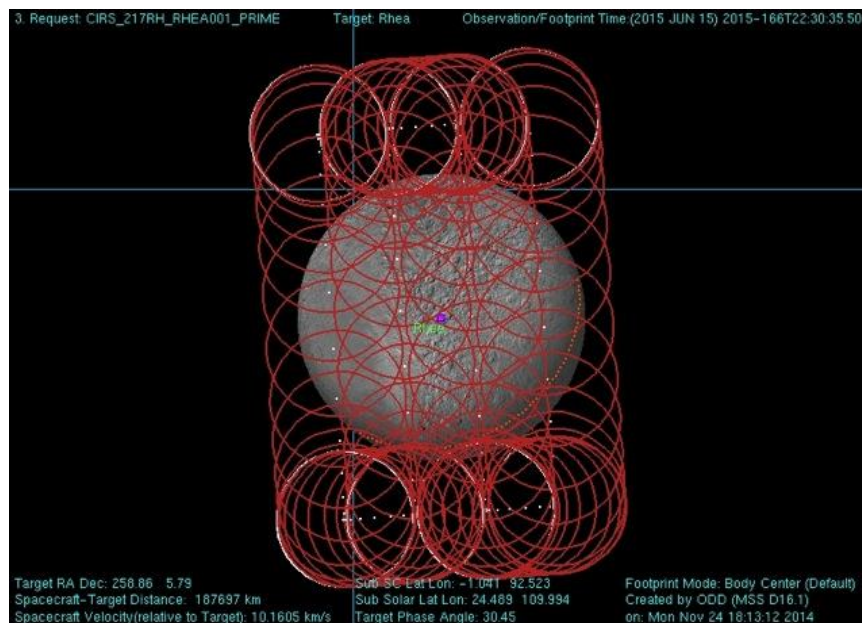

Figure 1 – Typical FP1 raster scan of a target. The FP1 footprints are shown in red, in this case the target is Rhea during Rev 217.

### Scans across a scene of interest

Occasionally a single scan of FP1 was made across a scene of interest. This usually occurred if the time allocated to CIRS was limited, and the scene was of scientific interest. An example of such scans is given in Figure 2 (across Rhea's south pole, and along one of Enceladus' tiger stripes). The scan rates for these observations depended upon the size of the scene to be covered, the time allocated to CIRS, and the total objectives to be achieved during that time. Scan rates rarely exceeded 40  $\mu\text{rad/s}$ .

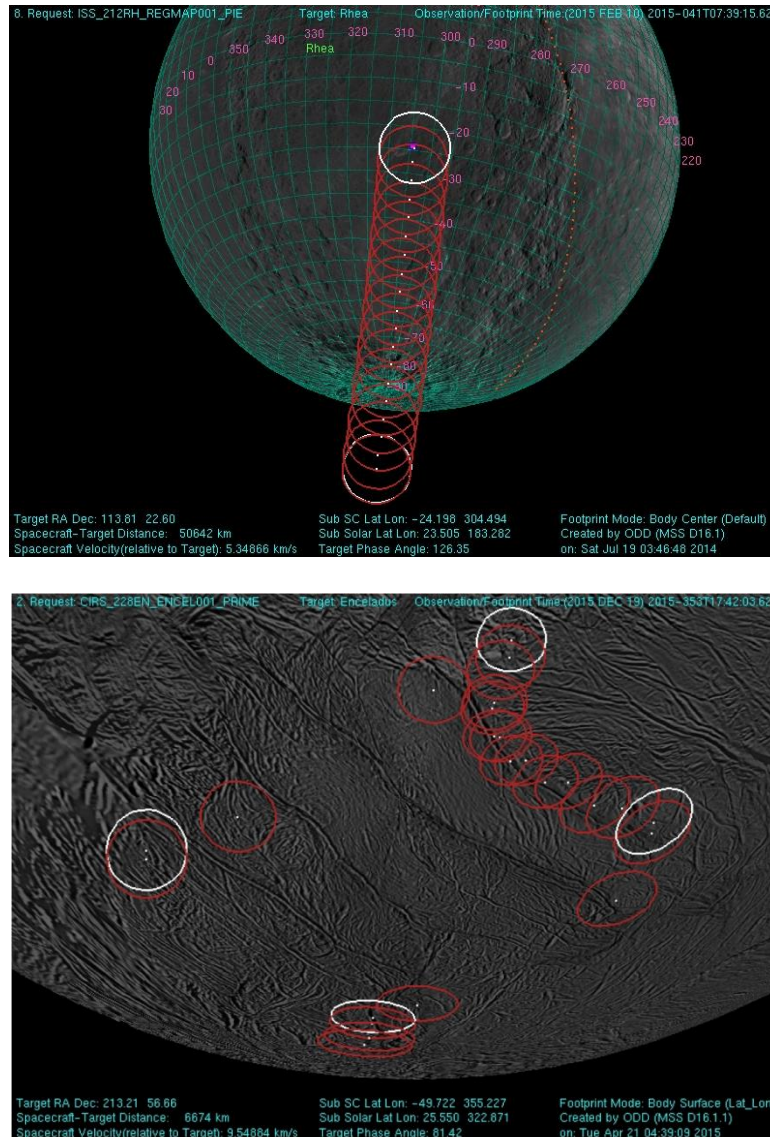

Figure 2. Top: Scanning FP1 across a scene of interest (Rhea's south pole during Rev

212). Bottom: Scanning FP1 along specific regions (Enceladus' tiger stripes during E22)

*Stares (including eclipse observations and the COMPGLBL campaign)*

To build up a higher signal to noise observations sometimes FP1 stare observations were made. These were occasionally done of small regions of a target (e.g. during Revs 61 and 90 for Enceladus South Polar Terrain), or to see how the surface temperature of a region changes during eclipse ingress and/or egress. Eclipse “season” for each of the satellites is given below. During these times CIRS made a concerted effort to observe each satellite over an eclipse, typically with FP1 (although FP3/4 were often riding).

A comprehensive and systematic set of FP1 stare observations were taken as part of the COMPGLBL campaign. This campaign came about because CIRS ring scientists made a large number of FP1 observations of the rings to characterize and compare spectral features and emissivity across distinct ring regions. COMPGLBL observations of icy satellites were designed to be compatible with those ring observations, to allow the emissivity of Saturn’s rings and icy satellites to be compared. Specifically these observations were long FP1 stares with a FOV filling factor on an icy satellite  $\approx 0.25 - 1$ . They then also included a FP3 scan to allow for temperature mapping. An example of such FP1 stares is given in Figure 3

Satellite	Start of Eclipse Season	End of Eclipse Season
Mimas	17 <sup>th</sup> May 2006	15 <sup>th</sup> Jan 2013
Tethys	23 <sup>rd</sup> Oct 2007	19 <sup>th</sup> Oct 2011
Enceladus	14 <sup>th</sup> Mar 2007	19 <sup>th</sup> Feb 2012
Dione	19 <sup>th</sup> Feb 2008	18 <sup>th</sup> Feb 2011
Rhea	5 <sup>th</sup> Jul 2008	4 <sup>th</sup> Sep 2010
Iapetus	14 <sup>th</sup> Feb 2007	5 <sup>th</sup> May 2007

Table 1 – Eclipse season start and end times for Saturn’s major icy satellites.

### FP3 and FP4 observing strategies.

#### *Introduction*

CIRS has ten detectors on FP3 and FP4, however only five can be read out at any one time. For most icy satellite observations we use FP3 and FP4 in blink mode (i.e. first even numbered FP3/4 detectors are read out, then in the next observation the odd ones are read out). This way spatial resolution is not lost (unlike in pairs mode, where neighboring detectors are paired together and these five pairs are read out simultaneously). There is also another mode (which was rarely/never used in icy satellite observations) called pairs mode, where only the five central detectors were read out.

As already mentioned FP3 and FP4 often observed together, when data volume allowed. Since FP4 less sensitive to cooler temperatures it was the first to be dropped. Both FP3 and FP4 require regularly

“shutter closed” observations to be made, so their data can be well calibrated. The length of time to take these shutter closed calibrations depended upon the spectral resolution of the data being taken, but was typically less than ~ 3 minutes. Time observing deep space also aided the FP3 and FP4 calibrations, and so typically the scans were made to include some off-target observations.

Wavenumber Resolution (cm-1)	FP3/4 mode	Shutter closed time (mm:ss.00)
15	Blink	01:52.625
15	Pairs	01:03.750
2.85	Blink	04:24.875
2.85	Pairs	02:23.500

Table 1- Shutter closed times for FP3/4 observations for different modes, for different wavenumber resolution. Note FP3 and FP4 shutter closed were taken simultaneously. Note these times assume no on-board co-adding of spectra. (Pairs and centers mode require the same shutter closed time)

***Typical scanning strategy***

Unless data volume was constrained when FP3 was used we typically used FP4 too. An optimal FP3/FP4 observation was to start detecting deep space with both detectors, then slowly (~6  $\mu$ rad/s) scan the detectors over the target so far that both detectors were back on deep space at the end of the scan. When observations were made close to the target sometimes these scans consisted of more than one swath (typically two, but not three). In this case the scans went back and forth over the target (i.e. swept over the target to deep space, and then back again to deep space). The slow scan rate was used to allow other remote sensing instruments to ride on these scans (particularly VIMS). A typical FP3/4 and FP3 observation is given in Figure 4.

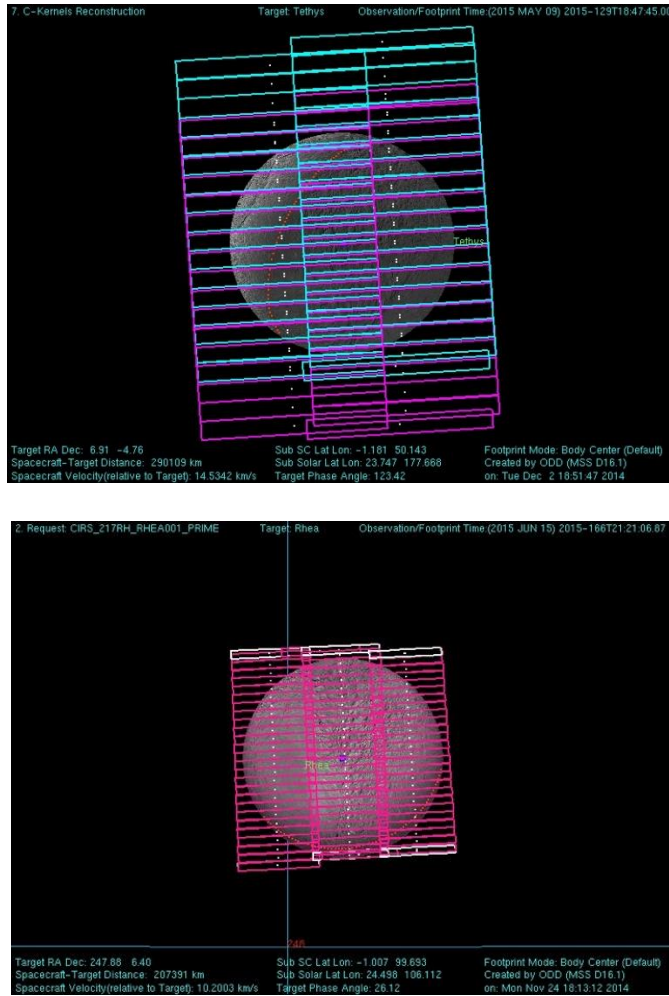

Figure 4 – Top: Typical FP3 and FP4 observing strategies (this one is of Tethys during Rev 215), and FP3 alone observing strategy (Rhea during Rev 217)

*Specific region scanning*

If CIRS was given time to observe a partially-lit target then FP3/4 were sometimes used to observe just its dayside. Typically one to three swaths were made across the daylight portion of the target to build up spatial coverage. Examples of such observations are given in Figure 5, against both Saturn and dark sky.

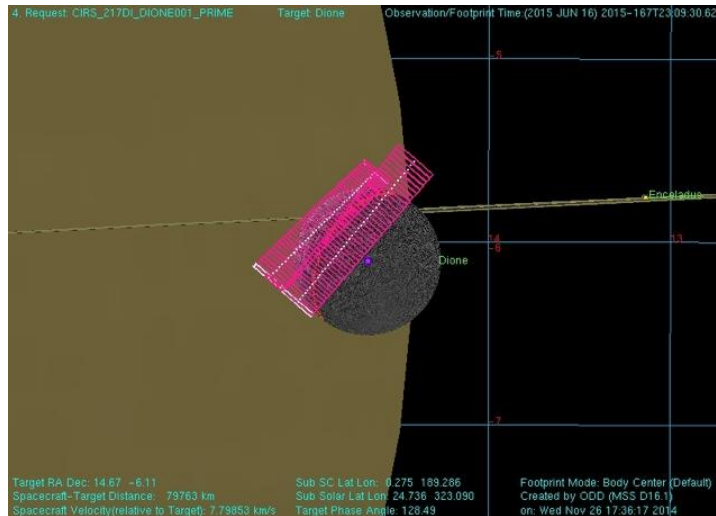

Figure 5 – FP3 observations of the daylight portion of a target. Top – Dione during Rev 217 against Saturn, Bottom – Dione during Rev 217 against dark sky.

Sometimes FP3/4 were scanned across specific regions of interest to determine their surface temperatures. Most notably this was done for Enceladus’ active tiger stripes, where FP3/4 observations provided higher spatial resolution observations than FP1 but still good signal to noise (because of the high surface temperature of that region). However, it was also done over other regions of interest (e.g. polar regions or Rhea’s equator in potential ring-infall regions (see Figure 6).

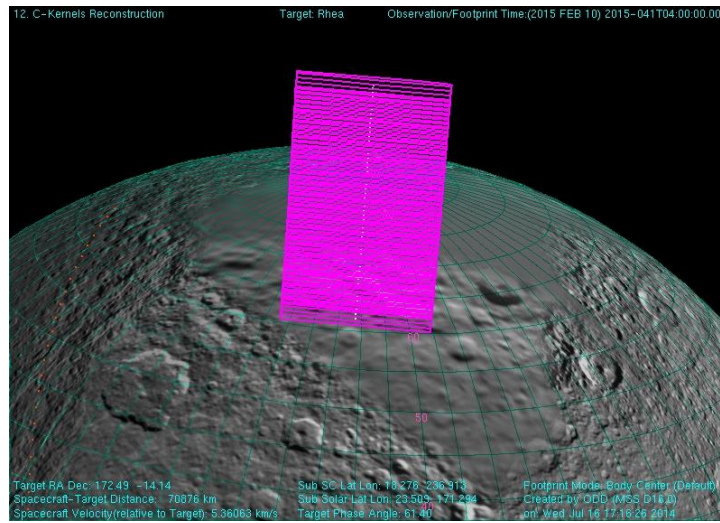

Figure 6 – FP3 observations of specific target regions. Top – across Rhea’s equator looking for evidence of thermal changes on across it’s blue-spotted equatorial belt. Bottom – across Rhea’s northern pole, limb and onto deep space (both taken during Rev 212).

### *Mean Anomaly Coverage*

During Cassini’s F-Ring and Proximal orbits (FRPO) an effort was made to make FP3 observations of Enceladus’ south polar terrain at different mean anomalies, to determine whether Enceladus’ thermal emission varied with time. These observations had the same format: a distant slow scan of Enceladus’ south polar terrain. Plenty of margin was given in these observations to ensure the target was covered. The scans were typically slow ( $6 \mu\text{rad/s}$ ) at  $15 \text{ cm}^{-1}$  spectral resolution. An example of these scans is given in Figure 7.

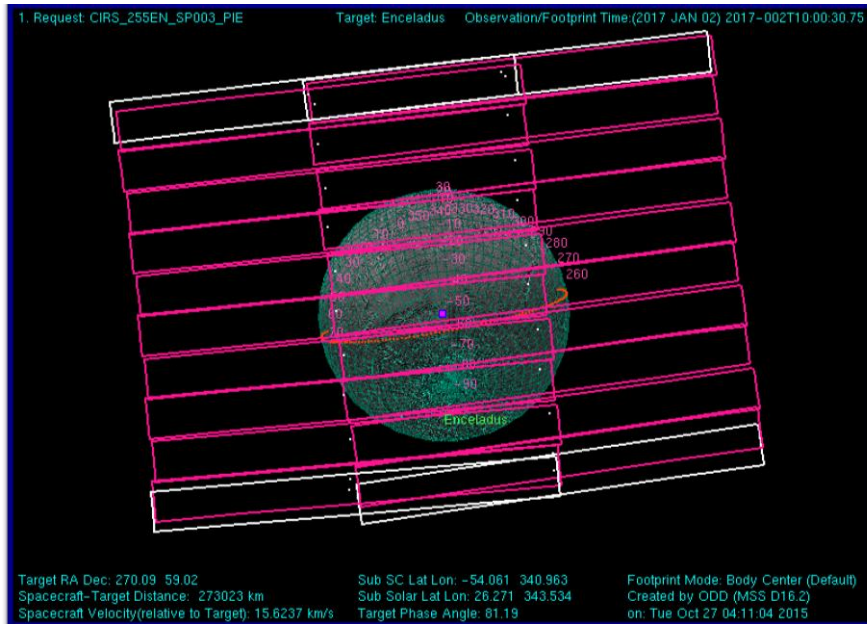

Figure 7 – A typical FP3 observation of Enceladus’ south polar terrain taken as part of the FRPO SP0XX campaign to obtain mean anomaly coverage. This observation was taken during Rev 255 (i.e. SP003).

### *Small satellite observations*

Saturn’s small moons (e.g. ring moons) were typically too small to resolve with FP1, and so typically scans of such moons were made by FP3 and FP4. The length of the scan depended on the geometry, but typically they were made following the same technique as a larger-satellite encounter (i.e.  $6 \mu\text{rad/s}$ ,  $15 \text{ cm}^{-1}$  spectral resolution, with dark sky before and after). Since they were small typically only one swath was required to achieve full coverage. A typical CIRS observation of a small satellite is given in Figure 8.

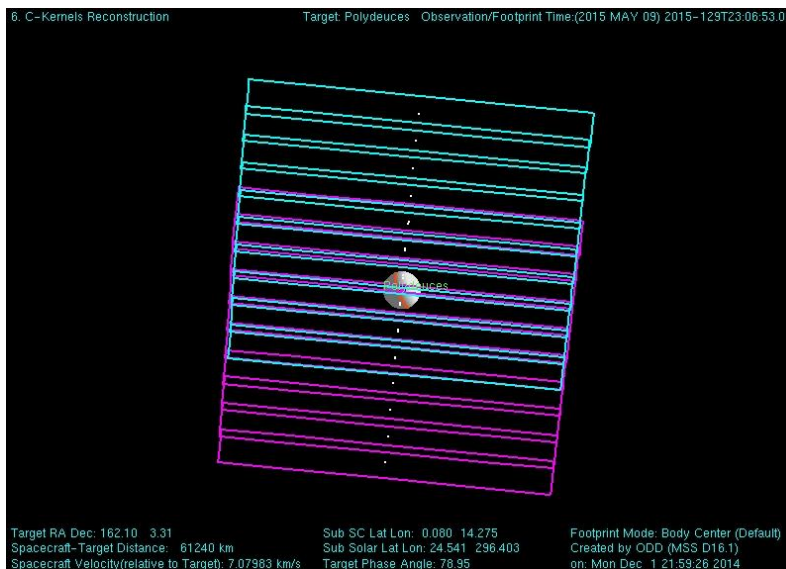

Figure 8 – CIRS FP3 and FP4 observation of Polydeuces.

## **Rider observations**

### ***Background to Riders***

There are two types of CIRS riders, one when the pointing is prioritized for one focal plane, but CIRS still uses all focal planes (for example when an FP3 scan is designed, but FP1 also records data). Under this rider-scenario CIRS could tweak the design to ensure all focal planes were able to obtain data. An example of this was FP3/4 during eclipse observations, when the pointing of FP1 was considered prime, but was set so FP3/4 were also on the target and not off the limb.

The second scenario occurred when another remote sensing instrument was prime. During this time CIRS simply “got what we could”! This meant using FP3/FP4 for daytime observations (if data volume was limited then FP4 was lost first), and FP1 for nighttime observations. We had little input on where the CIRS field of views were scanned, or how. There were some exceptions to this however, which are explored below.

### ***Enceladus’ blip observations***

There were unique sets of rider observations made of Enceladus’ active regions. These observations were made on INMS and gravity passes when Cassini was passing very close (<50 km) above Enceladus’ active regions. Since the ground-track speed of the spacecraft was fast a single CIRS observation was smeared over ~48 km. However, somewhat by accident we realized that CIRS could detect scene changes in its interferogram. Specifically in Rev 120 (Nov 2009) “blips” occurred when the temperature of the observed scene changed dramatically (e.g. over a tiger stripe, or across a limb). So the observation strategy changed in Rev 164 and 224 to making long (~50 s) scans, which mostly covered the full disk. These observations were made because it was hoped that the change of signal with time could be translated to distance, i.e. to show how much the temperature of the scene had changed. It was found that to do this properly the onboard processing software had to be modified to be able to disable the onboard numerical filtering. Post-Rev 164 observations (i.e. Rev 224) were made with this change. This work is complicated and continues!

### ***CIRS-specific scans in rider observations***

To simplify sequencing during short encounters with a target sometimes a single instrument was made prime, but liens were put on their observing time to include scans specifically for other instruments. This tactic was often used for observations of small satellites (for example Saturn’s ring moons), when ISS was prime but CIRS would request specific scans. These CIRS scans typically had the same format as a CIRS prime observation of a small moon (i.e. as described above, and shown in Figure 8).

## Planning

This section of the Icy Satellite target notebook contains a detailed view of the observation planning, design, and development as they were prepared and intended to execute on the spacecraft. It is important to note that the user MAY find small differences in pointing or timing between what was planned and what executed on board. CIRS planned 1114 observations of the major Icy Satellites over the course of the Cassini mission which are in the time ordered listings included in this section. For user ease, each satellite – Phoebe, Dione, Enceladus, Hyperion, Tethys, Mimas, Iapetus, and Rhea – have individual time ordered listings.

The time ordered listing contains the name, the start time, duration, and end time for each Icy satellite observation. If the observation was within a moveable block of time, there will be an entry in the Epoch column – a simplistic way to use this information is as an alert to the user that there may be a shift in the start and end time due to a change in the time of closest approach to the target (time of flight error).

The name itself gives much information about the observation. The naming convention is complex enough that a decoder ring has been provided below:

In the example of CIRS\_003EN\_FP1FP3MAP001\_PRIME, CIRS (first 4 characters indicate the instrument that is collecting data); 000EN (second group of 5 characters indicate the Cassini revolution or orbit number is 003 and the target id – in this case EN is Enceladus); FP1FP3MAP001 (the third group of 10 characters indicates that this observation is a temperature map and that it is the first in a series of similar/repeatable observations in the revolution or orbit); PRIME (the last 5 characters indicate that CIRS controlled the pointing of the spacecraft for this observation).

It is important to note that in many cases CIRS collected data while other instruments controlled the pointing – this category of observations were called “riders” or “collaborative riders”. This class of observations are easily identified by the last few characters in the observation name – ie UVIS, VIMS, ISS, SI (support imaging), and RIDER.

For each observation in the time ordered listing, there exists ancillary data that was generated during the integration and implementation process. There is a graphical image (ODD plot) that depicts the target at some point of time in the observation – this can give the user a quick look at the placement and spatial resolution of the CIRS field of views. The planned pointing and instrument commanding can be viewed in the shortform (sfof) text file. The planned c-kernels (ck) provide the highest level of detailed pointing available for the observation. Cubes exist for all the observations and are delivered with our data to the atmospheric node of PDS however we are providing those for all the CIRS rider observations as capturing all the ancillary files for each rider was very time consuming and out of the scope of our budget. These files are all accessible by hyper-link from the time-ordered listing.

In addition, rows in the TOL highlighted in orange are observations lost in execution due to instrument or spacecraft anomaly. Details are available in the Database section of this handbook.

## Database Contents

**MORE work here!!!!**

Brief discussion about what is in the database, what was calibrated, what wasn't and why. Itemize observations that were lost due to instrument anomaly, rwa interference, etc... ..

Target	On the Ground	Calibrated	% Cal
Deep Space	76,840,919	72,727,153	94.65%
Titan	10,948,860	10,516,664	96.05%
Saturn	29,821,717	29,438,506	98.71%
Rings	40,646,344	40,210,295	98.93%
Icy Satellite	7,305,025	7,067,012	96.74%
Stellar	122,533	121,824	99.42%
Shutter	5,650,373	5,163,276	91.38%
Total	<b>171,335,771</b>	<b>165,244,730</b>	<b>96.44%</b>

## Publications and Science Research

A list of science publications (with links if we can make that happen) and a brief description of the science analysis that has been done and contact info for those on the team involved. This enables some dialogue where it needs to happen and a means for the user to quickly access the publications without having to do an exhaustive search...
